

Preconditioning of a coupled Cahn–Hilliard Navier–Stokes system

Jessica Bosch* Christian Kahle[†] Martin Stoll[‡]

October 14, 2016

Abstract

Recently, Garcke et al. [GHK16] developed a consistent discretization scheme for a thermodynamically consistent diffuse interface model for incompressible two-phase flows with different densities. At the heart of this method lies the solution of large and sparse linear systems that arise in a semismooth Newton method.

We propose the use of preconditioned Krylov subspace solvers using effective Schur complement approximations. Numerical results illustrate the efficiency of our approach. In particular, our preconditioner is shown to be robust with respect to parameter changes.

Keywords: Navier–Stokes, Cahn–Hilliard, two-phase flow, preconditioning, Schur complement approximation

1 Introduction

This work deals with Abels et al.’s [AGG12] diffuse interface model for incompressible two-phase flows with different densities, which is described below in Section 2. It couples the Navier–Stokes equations to the Cahn–Hilliard model in a thermodynamically consistent way, i.e., an energy inequality holds, and is based on a phase field representation of the binary fluid structure.

The Cahn–Hilliard equation is a partial differential equation of fourth order, which is used in materials science [NC98, Gar05], image processing [DVM02], or chemistry [WD08]. It was originally introduced to model phase separation in binary alloys [CH58] that occurs when the temperature of a homogeneous mixture is rapidly quenched below a critical temperature.

Recently, Garcke et al. [GHK16] developed a thermodynamically consistent discretization scheme for the two-phase flow equation under consideration. At the heart of this method lies the solution of linear systems $\mathcal{A}z = b$ with a real nonsymmetric coefficient matrix of the form

$$\mathcal{A} = \left(\begin{array}{c|c} A_{\text{NS}} & C_I \\ \hline C_T & A_{\text{CH}} \end{array} \right) = \left(\begin{array}{cc|cc} A & B^t & 0 & U \\ B & 0 & 0 & 0 \\ \hline T & 0 & \alpha M & \beta K \\ 0 & 0 & L & -M \end{array} \right).$$

The blocks $A_{\text{NS}} \in \mathbb{R}^{(N_1+2N_2) \times (N_1+2N_2)}$ and $A_{\text{CH}} \in \mathbb{R}^{2N_1 \times 2N_1}$ are the discrete realizations of the linearized Navier–Stokes and Cahn–Hilliard system, respectively. Their coupling is represented by C_I , the coupling through interfacial forces, and C_T , the coupling through the transport at the interface. The sparse linear systems are usually of very large dimension, and in combination with three-dimensional experiments, the application of direct solvers such as UMFPACK [Dav16] becomes infeasible. As a result, iterative methods have to be employed (see, e.g., [Gre97, Saa03] for introductions to this field). We propose the use of Krylov subspace solvers. The convergence behavior of the iterative schemes typically depends on the conditioning of the problem and the clustering of the eigenvalues. These properties are usually affected by the model parameters. Various parameters of different scales are involved in $\mathcal{A}$: Spatial mesh sizes, the time step size, the interfacial parameter, the mobility of the interface, a penalty parameter, the Reynolds number, and the surface tension. The convergence behavior of the iterative schemes can be enhanced using preconditioning techniques $\mathcal{A}\mathcal{P}^{-1}\tilde{z} = b$ or $\mathcal{P}^{-1}\mathcal{A}z = \mathcal{P}^{-1}b$, where $\mathcal{P}$ is an invertible matrix that is easy to invert and resembles $\mathcal{A}$. In this paper, we provide an efficient preconditioner $\mathcal{P}$ tailored to the coupled Cahn–Hilliard Navier–Stokes system using effective Schur complement approximations and (algebraic) multigrid developed for elliptic systems [Fal06, Saa03, RS87]. In particular, our preconditioner is shown to be robust with respect to parameter changes.

The paper is organized as follows. In Section 2, we introduce the two-phase flow equation under consideration. We state the thermodynamically consistent discretization proposed in [GHK16] and review major analytical results. In Section 3, we develop and investigate our preconditioner, while in Section 4, we show its performance in a benchmark example and investigate its robustness with respect to the relevant parameters of the system under investigation. Finally, Section 5 summarizes our findings.

2 The Cahn–Hilliard Navier–Stokes model

In [AGG12], the following thermodynamically consistent diffuse interface model for the simulation of two-phase fluids with different densities is proposed:

Let $\Omega \subset \mathbb{R}^n$, $n \in \{2, 3\}$ denote an open, bounded domain with Lipschitz boundary and outer normal ν_Ω , and $I = (0, T]$ denote a time interval. Inside Ω

there are two immiscible phases and we introduce a smooth indicator function φ , called phase field, such that $\varphi \approx +1$ indicates the one phase and $\varphi \approx -1$ indicates the second phase. The values $|\varphi| \leq 1$ indicate a diffuse interface between the phases. The velocity and the pressure of the fluid are denoted by v and p ; see [AGG12] for the precise definition of this terms. Adding a chemical potential μ as derivative of the underlying Ginzburg–Landau energy, the model is given by the following set of equations:

$$\begin{aligned}
\rho \partial_t v + ((\rho v + J) \cdot \nabla) v - \operatorname{div}(2\eta Dv) + \nabla p &= \mu \nabla \varphi + \rho g & \forall x \in \Omega, \forall t \in I, & \quad (1) \quad \{\text{eq:CHNS:CHNSstrong1}\} \\
-\operatorname{div}(v) &= 0 & \forall x \in \Omega, \forall t \in I, & \quad (2) \quad \{\text{eq:CHNS:CHNSstrong2}\} \\
\partial_t \varphi + v \cdot \nabla \varphi - b \Delta \mu &= 0 & \forall x \in \Omega, \forall t \in I, & \quad (3) \quad \{\text{eq:CHNS:CHNSstrong3}\} \\
-\sigma \epsilon \Delta \varphi + \frac{\sigma}{\epsilon} W'(\varphi) - \mu &= 0 & \forall x \in \Omega, \forall t \in I, & \quad (4) \quad \{\text{eq:CHNS:CHNSstrong4}\} \\
v(0, x) &= v_0(x) & \forall x \in \Omega, & \quad (5) \quad \{\text{eq:CHNS:CHNSstrongIC1}\} \\
\varphi(0, x) &= \varphi_0(x) & \forall x \in \Omega, & \quad (6) \quad \{\text{eq:CHNS:CHNSstrongIC2}\} \\
v(t, x) &= 0 & \forall x \in \partial\Omega, \forall t \in I, & \quad (7) \quad \{\text{eq:CHNS:CHNSstrongBC1}\} \\
\nabla \mu(t, x) \cdot \nu_\Omega = \nabla \varphi(t, x) \cdot \nu_\Omega &= 0 & \forall x \in \partial\Omega, \forall t \in I, & \quad (8) \quad \{\text{eq:CHNS:CHNSstrongBC2}\}
\end{aligned}$$

with $J = -\frac{\rho_2 - \rho_1}{2} b \nabla \mu$.

Here $\rho = \rho(\varphi) := \frac{\rho_2 - \rho_1}{2} \varphi + \frac{\rho_2 + \rho_1}{2}$ describes the interpolated density of the fluid, and $\eta = \eta(\varphi) := \frac{\eta_2 - \eta_1}{2} \varphi + \frac{\eta_2 + \eta_1}{2}$ the interpolated viscosity, where ρ_1, ρ_2 are the densities of the two pure phases, while η_1, η_2 are the corresponding viscosities. By $2Dv = \nabla v + (\nabla v)^t$ we denote the symmetrized gradient. The gravitational force is denoted by g . By b we denote the constant mobility of the interface. The scaled surface tension (see [AGG12, Sec. 4.3.4]) is given by σ and the interfacial region between the phases has a thickness of order $O(\epsilon)$. The free energy density of the interface is denoted by W and here we use

$$W(\varphi) = W^s(\varphi) = \frac{1}{2} \left(1 - \varphi^2 + s \max(0, \varphi - 1)^2 + s \min(0, \varphi + 1)^2 \right),$$

where $s \gg 0$ denotes a relaxation coefficient arising from the Moreau–Yosida relaxation of the double-obstacle free energy

$$W^\infty(\varphi) = \begin{cases} \frac{1}{2}(1 - \varphi^2) & \text{if } |\varphi| \leq 1, \\ +\infty & \text{else;} \end{cases}$$

see [BE91, HHT11]. Note that the results proposed in [GHK16] are valid for a wider class of free energy densities. Finally, the initial velocity is given by v_0 and the initial phase field by φ_0 . Note that for simplicity we use a no-slip boundary condition for the velocity field.

Concerning existence and uniqueness of solutions, we refer to [ADG13a, ADG13b, Grü13].

Assumption 1.

- There exist $0 < \underline{\rho} \leq \bar{\rho} < +\infty$ such that $\underline{\rho} \leq \rho(\varphi) \leq \bar{\rho}$. Due to the linear nature of the function $\rho(\varphi)$, this essentially is a $L^\infty(\Omega)$ bound on the phase field φ .
- There exist $0 < \underline{\eta} \leq \bar{\eta} < +\infty$ such that $\underline{\eta} \leq \eta(\varphi) \leq \bar{\eta}$. Due to the linear nature of the function $\eta(\varphi)$, this also is a $L^\infty(\Omega)$ bound on the phase field φ .

For our choice of the free energy, in [HSW14, Kah15] it is shown that

$$\|\varphi\|_{L^\infty(\Omega)} \leq Cs^{-1}$$

holds, and thus in the following we assume that Assumption 1 is fulfilled. This is also reflected later by requiring L^∞ regularity for the phase field φ in the definition of the time discrete equations.

Let us next derive the weak formulation proposed in [GHK16]. Using the linearity of ρ , one can reformulate (1) as

$$\partial_t(\rho v) + \operatorname{div}(v \otimes (\rho v + J)) - \operatorname{div}(2\eta Dv) + \nabla p = \mu \nabla \varphi + \rho g. \quad (9) \quad \{\text{eq:CHNS:CHNSstrong1_2}\}$$

Using the sum of (1) and (9), the following weak formulation of (1)–(8) is proposed in [GHK16].

Definition 2. We call v, p, φ, μ a weak solution to (1)–(8) if $v(0) = v_0, \varphi(0) = \varphi_0$, and

$$\begin{aligned} & \frac{1}{2} \int_{\Omega} (\partial_t(\rho v) + \rho \partial_t v) w \, dx + \int_{\Omega} 2\eta Dv : Dw \, dx \\ & + a(\rho v + J, v, w) - (p, \operatorname{div} w) = \int_{\Omega} \mu \nabla \varphi w + \rho g w \, dx \quad \forall w \in H_0^1(\Omega)^n, \end{aligned} \quad (10) \quad \{\text{eq:CHNS:CHNS1_weak}\}$$

$$-(\operatorname{div} v, q) = 0 \quad \forall q \in L_{(0)}^2(\Omega), \quad (11) \quad \{\text{eq:CHNS:CHNS2_weak}\}$$

$$\int_{\Omega} (\partial_t \varphi + v \cdot \nabla \varphi) \Psi \, dx + \int_{\Omega} b \nabla \mu \cdot \nabla \Psi \, dx = 0 \quad \forall \Psi \in H^1(\Omega), \quad (12) \quad \{\text{eq:CHNS:CHNS3_weak}\}$$

$$\sigma \epsilon \int_{\Omega} \nabla \varphi \cdot \nabla \Phi \, dx + \frac{\sigma}{\epsilon} \int_{\Omega} W'(\varphi) \Phi \, dx - \int_{\Omega} \mu \Phi \, dx = 0 \quad \forall \Phi \in H^1(\Omega), \quad (13) \quad \{\text{eq:CHNS:CHNS4_weak}\}$$

is satisfied for almost all $t \in I$.

Here, for $u \in L^3(\Omega)^n, v, w \in H^1(\Omega)^n$, we define the antisymmetric trilinear form

$$a(u, v, w) := \frac{1}{2} \left(\int_{\Omega} ((u \nabla) v) w \, dx - \int_{\Omega} ((u \nabla) w) v \, dx \right),$$

and by $L_{(0)}^2(\Omega)$ we denote the space of square integrable functions with mean value zero, i.e.

$$L_{(0)}^2(\Omega) := \{f \in L^2(\Omega) \mid |\Omega|^{-1} \int_{\Omega} f \, dx = 0\}.$$

Definition 3. *The energy of the system is the sum of the kinetic energy of the fluid and the Ginzburg–Landau energy of the interface. Thus we define*

$$E(v, \varphi) := \frac{1}{2} \int_{\Omega} \rho |v|^2 dx + \frac{\sigma \epsilon}{2} \int_{\Omega} |\nabla \varphi|^2 dx + \frac{\sigma}{\epsilon} \int_{\Omega} W(\varphi) dx. \quad (14)$$

Theorem 4 ([GHK16, Thm. 1]). *Assume that there exists a sufficiently smooth solution to (10)–(13).*

Then, the following energy equality holds:

$$\frac{d}{dt} \left(\int_{\Omega} \frac{\rho}{2} |v|^2 + \frac{\sigma \epsilon}{2} |\nabla \varphi|^2 + \frac{\sigma}{\epsilon} W(\varphi) dx \right) = - \int_{\Omega} 2\eta |Dv|^2 + b |\nabla \mu|^2 dx + \int_{\Omega} \rho g v dx. \quad (15)$$

2.1 Results for the time discrete setting

In this section, we state the stable time discretization proposed in [GHK16], and briefly review analytical results.

Let $t_{-1} < 0 = t_0 < t_1 < \dots < t_{k-2} < t_{k-1} < t_k < \dots < t_K = T$ denote an equidistant subdivision of $I = (0, T]$ with fix step size $\tau := t_1 - t_0$. We define $\varphi^k := \varphi(t_k)$, $\mu^k := \mu(t_k)$, $v^k := v(t_k)$, and $p^k := p(t_k)$ as well as $\rho^k := \rho(\varphi^k)$, and $\eta^k := \eta(\varphi^k)$. We use the following time discrete variant of (1)–(8):

Let $\varphi^{-1}, \varphi^0 \in H^1(\Omega) \cap L^\infty(\Omega)$, $\mu^0 \in W^{1,3}(\Omega)$, and $v^0 \in H^1(\Omega)$ be given. For $k = 1, \dots, K$, find $v^k \in H_0^1(\Omega)^n$, $p^k \in L_{(0)}^2(\Omega)$, $\varphi^k \in H^1(\Omega) \cap L^\infty(\Omega)$, $\mu^k \in W^{1,3}(\Omega)$ satisfying

$$\begin{aligned} & \frac{1}{\tau} \int_{\Omega} \left(\frac{\rho^{k-1} + \rho^{k-2}}{2} v^k - \rho^{k-2} v^{k-1} \right) w dx \\ & + a(\rho^{k-1} v^{k-1} + J^{k-1}, v^k, w) + \int_{\Omega} 2\eta^{k-1} Dv^k : Dw dx \\ & - \int_{\Omega} p^k \operatorname{div} w dx - \int_{\Omega} \mu^k \nabla \varphi^{k-1} w - \rho^{k-1} g w dx = 0 \quad \forall w \in H_\sigma(\Omega), \quad (16) \quad \{\text{eq:TD:chns1}\} \end{aligned}$$

$$- \int_{\Omega} \operatorname{div} v^k q dx = 0 \quad \forall q \in L_{(0)}^2(\Omega), \quad (17) \quad \{\text{eq:TD:chns2}\}$$

$$\begin{aligned} & \frac{1}{\tau} \int_{\Omega} (\varphi^k - \varphi^{k-1}) \Psi dx + \int_{\Omega} \varphi^{k-1} v^k \cdot \nabla \Psi dx \\ & + \int_{\Omega} b \nabla \mu^k \cdot \nabla \Psi dx = 0 \quad \forall \Psi \in H^1(\Omega), \quad (18) \quad \{\text{eq:TD:chns3}\} \end{aligned}$$

$$\begin{aligned} & \sigma \epsilon \int_{\Omega} \nabla \varphi^k \cdot \nabla \Phi dx - \int_{\Omega} \mu^k \Phi dx \\ & + \frac{\sigma}{\epsilon} \int_{\Omega} ((W_+)'(\varphi^k) + (W_-)'(\varphi^{k-1})) \Phi dx = 0 \quad \forall \Phi \in H^1(\Omega), \quad (19) \quad \{\text{eq:TD:chns4}\} \end{aligned}$$

where $J^{k-1} := -\frac{\rho_2 - \rho_1}{2} b \nabla \mu^{k-1}$. By $W_+(\varphi) = \frac{\sigma}{2}(\max(0, \varphi - 1)^2 + \min(0, \varphi + 1)^2)$ we denote the convex part of W , and by $W_-(\varphi) = \frac{1}{2}(1 - \varphi^2)$ we denote the concave part.

Concerning other time discretizations see, e.g., [GT14, GK14, Ala14, HKW15].

Remark 5. Note that (16) – (19) is a two-step scheme since it requires data from t_{k-2} and t_{k-1} to evaluate the solution at time t_k . Especially, we require the somewhat artificial data φ^{-1} . In [GHK16], a one-step scheme with a different time discretization is proposed for the initialization of the two-step scheme (16) – (19). Here, we argue as in [HKW15] that given φ^{-1} and v^0 one can solve (18) – (19) to obtain the missing data φ^0 and μ^0 to start the two-step scheme. See also [GHK16, Rem. 3]

Theorem 6 ([GHK16, Rem. 3, Thm. 6, Thm. 7]). Let $\varphi^{k-2}, \varphi^{k-1} \in H^1(\Omega) \cap L^\infty(\Omega)$, $\mu^{k-1} \in W^{1,3}(\Omega)$, and $v^{k-1} \in H_0^1(\Omega)^n$ be given.

Then there exists a unique solution $v^k \in H_0^1(\Omega)^n$, $p^k \in L_{(0)}^2(\Omega)$, $\varphi^k \in H^1(\Omega) \cap L^\infty(\Omega)$, $\mu^k \in W^{1,3}(\Omega)$ to (16) – (19).

Moreover, this solution can be found by Newton's method in function space and fulfills the following energy inequality:

$$\begin{aligned} & \frac{1}{2} \int_{\Omega} \rho^{k-1} |v^k|^2 dx + \frac{\sigma \epsilon}{2} \int_{\Omega} |\nabla \varphi^k|^2 dx + \frac{\sigma}{\epsilon} \int_{\Omega} W(\varphi^k) dx \\ & + \frac{1}{2} \int_{\Omega} \rho^{k-2} |v^k - v^{k-1}|^2 dx + \frac{\sigma \epsilon}{2} \int_{\Omega} |\nabla \varphi^k - \nabla \varphi^{k-1}|^2 dx \\ & + \tau \int_{\Omega} 2\eta^k |Dv^k|^2 dx + \tau \int_{\Omega} b |\nabla \mu^k|^2 dx \\ & \leq \frac{1}{2} \int_{\Omega} \rho^{k-2} |v^{k-1}|^2 dx + \frac{\sigma \epsilon}{2} \int_{\Omega} |\nabla \varphi^{k-1}|^2 dx + \frac{\sigma}{\epsilon} \int_{\Omega} W(\varphi^{k-1}) dx \\ & + \int_{\Omega} \rho^{k-1} g v^k dx. \end{aligned}$$

We now come to the discretization of (16)–(19) in space.

2.2 Results for the fully discrete setting

For a numerical realization, let us next discretize (16)–(19) in space using the finite element method. For this, let $\mathcal{T}^k = \{T_1, \dots, T_N\}$ denote a conforming triangulation of $\overline{\Omega}$ with cells $(T_i)_{i=1}^N$, where we assume that $\overline{\Omega} = \bigcup_{i=1}^N T_i$. Here, superscript k refers to the time instance, and we note that we use different triangulations on different time instances due to adaptive meshing. On $\mathcal{T}^k$, we define the finite element spaces

$$\begin{aligned} V_1^k &:= \{v \in C(\overline{\Omega}) \mid v|_T \in P^1(\Omega) \forall T \in \mathcal{T}^k\} =: \text{span}\{b_1^i\}_{i=1}^{N_1}, \\ V_2^k &:= \{v \in C(\overline{\Omega})^n \mid v|_T \in (P^2(\Omega))^n \forall T \in \mathcal{T}^k, v|_{\partial\Omega} = 0\} =: \text{span}\{b_2^i\}_{i=1}^{N_2}. \end{aligned}$$

Here, P^l denotes the space of polynomials up to order l . We note that $V_k^1 \subset W^{1,\infty}(\Omega)$ and $V_k^2 \subset W^{1,\infty}(\Omega)^n$. We further introduce an H^1 -stable prolongation operator $P^k : H^1(\Omega) \rightarrow V_1^k$ satisfying

$$\|P^k v\|_{L^p(\Omega)} \leq \|v\|_{L^p(\Omega)} \quad \|\nabla P^k v\|_{L^r(\Omega)} \leq \|\nabla v\|_{L^r(\Omega)}$$

for $r \in [1, 2]$ and $p \in [1, 6]$ if $n = 3$ and $p \in [1, \infty)$ if $n = 2$. Possible operators are, e.g., the Clément operator [Clé75] or Lagrangian interpolation, where we have to restrict the preimage to $C(\overline{\Omega}) \cap H^1(\Omega)$.

We denote by $\varphi_h^k \in V_k^1$ the fully discrete counterpart of φ^k , by $\mu_h^k \in V_k^1$ we denote the fully discrete counterpart of μ^k , by $v_h^k \in V_k^2$ we denote the fully discrete counterpart of v^k , and by p_h^k we denote the fully discrete counterpart to p^k . Note that we use LBB-stable Taylor–Hood elements for the discretization of the Navier–Stokes equation.

The fully discrete variant of (16)–(19) is as follows.

Let $\varphi^{k-2} \in V_{k-2}^1$, $\varphi^{k-1} \in V_{k-1}^1$, $\mu^{k-1} \in V_{k-1}^1$, $v^{k-1} \in V_{k-1}^2$ be given. Find $\varphi^k \in V_k^1$, $\mu^k \in V_k^1$, $v^k \in V_k^2$, and $p_h^k \in V_k^1$ such that

$$\begin{aligned} \frac{1}{\tau} \left(\frac{\rho^{k-1} + \rho^{k-2}}{2} v_h^k - \rho^{k-2} v^{k-1}, w \right) + a(\rho^{k-1} v^{k-1} + j^{k-1}, v_h^k, w) \\ + (2\eta^{k-1} Dv_h^k, Dw) - (p_h^k, \operatorname{div} w) - (\mu_h^k \nabla \varphi^{k-1} + \rho^{k-1} g, w) = 0, \forall w \in V_k^2 \end{aligned} \quad (20) \quad \{\text{eq:FD:chns1}\}$$

$$-(\operatorname{div} v_h^k, q) = 0 \forall q \in V_k^1, \quad (21) \quad \{\text{eq:FD:chns2}\}$$

$$\frac{1}{\tau} (\varphi_h^k - \mathcal{P}^k \varphi^{k-1}, \Psi) + (b \nabla \mu_h^k, \nabla \Psi) - (v_h^k \varphi^{k-1}, \nabla \Psi) = 0, \forall \Psi \in V_k^1, \quad (22) \quad \{\text{eq:FD:chns3}\}$$

$$\sigma \epsilon (\nabla \varphi_h^k, \nabla \Phi) + \frac{\sigma}{\epsilon} (W'_+(\varphi_h^k) + W'_-(\mathcal{P}^k \varphi^{k-1}), \Phi) - (\mu_h^k, \Phi) = 0, \forall \Phi \in V_k^1. \quad (23) \quad \{\text{eq:FD:chns4}\}$$

Theorem 7 ([GHK16, Thm. 2, Thm. 3]). *Let $\varphi^{k-2} \in V_{k-2}^1$, $\varphi^{k-1} \in V_{k-1}^1$, $\mu^{k-1} \in V_{k-1}^1$, $v^{k-1} \in V_{k-1}^2$ be given. Then there exists a unique solution $v_h^k \in V_k^2$, $\varphi_h^k, \mu_h^k, p_h^k \in V_k^1$ to (20)–(23) that fulfills the following energy inequality*

$$\begin{aligned} & \frac{1}{2} \int_{\Omega} \rho^{k-1} |v_h^k|^2 dx + \frac{\sigma \epsilon}{2} \int_{\Omega} |\nabla \varphi_h^k|^2 dx + \frac{\sigma}{\epsilon} \int_{\Omega} W(\varphi_h^k) dx \\ & + \frac{1}{2} \int_{\Omega} \rho^{k-2} |v_h^k - v^{k-1}|^2 dx + \frac{\sigma \epsilon}{2} \int_{\Omega} |\nabla \varphi_h^k - \nabla P^k \varphi^{k-1}|^2 dx \\ & + \tau \int_{\Omega} 2\eta^{k-1} |Dv_h^k|^2 dx + \tau \int_{\Omega} b |\nabla \mu_h^k|^2 dx \quad (24) \quad \{\text{eq:FD:energyInequality}\} \\ & \leq \frac{1}{2} \int_{\Omega} \rho^{k-2} |v^{k-1}|^2 dx + \frac{\sigma \epsilon}{2} \int_{\Omega} |\nabla P^k \varphi^{k-1}|^2 dx + \frac{\sigma}{\epsilon} \int_{\Omega} W(P^k \varphi^{k-1}) dx \\ & \quad + \tau \int_{\Omega} \rho^{k-1} g v_h^k. \end{aligned}$$

Moreover, this solution can be found by Newton's method.

Remark 8. Note that the energy inequality (24) bounds the energy at time instance k by the energy of $P^k \varphi^{k-1}$, i.e., the prolongation of φ^{k-1} to the triangulation $\mathcal{T}^k$, thus not by the energy at the old time instance. To overcome this, in [GHK16], a postprocessing step is added to the adaptive concept that guarantees that the energy does not increase through prolongation, where Lagrangian interpolation is used as prolongation P^k . Including this step, we guarantee that in absence of outer forces the energy of the system can not increase.

Theorem 7 states that we find the unique solution to (20)–(23) by Newton’s method. To state the algorithm, let us compactly write (20)–(23) as

$$\langle F(v_h^k, p_h^k, \varphi_h^k, \mu_h^k), (w, q, \Psi, \Phi) \rangle := \left((F^1(\dots), w), (F^2(\dots), q), (F^3(\dots), \Psi), (F^4(\dots), \Phi) \right)^t,$$

where $(F^1(\dots), w)$ abbreviates (20), $(F^2(\dots), \Psi)$ abbreviates (21), $(F^3(\dots), \Phi)$ abbreviates (22), and $(F^4(\dots), \Psi)$ abbreviates (23). Then Newton’s method generates the following sequence

$$\begin{aligned} DF(x^m) \delta x &= -F(x^m), \\ x^{m+1} &= x^m + \delta x, \quad m = 1, \dots \end{aligned} \tag{25} \quad \{\text{eq:FD:newtEq}\}$$

where x abbreviates $(v_h^k, p_h^k, \varphi_h^k, \mu_h^k)$. We note that F is due to our choice of W only Newton differentiable, see [HIK03]. A Newton derivative of F is given by

$$\begin{aligned} \langle DF(v_h^k, p_h^k, \varphi_h^k, \mu_h^k) (\delta v, \delta p, \delta \varphi, \delta \mu), (w, q, \Psi, \Phi) \rangle &:= \\ \frac{1}{\tau} \left(\frac{\rho^{k-1} + \rho^{k-2}}{2} \delta v, w \right) &+ a(\rho^{k-1} v^{k-1} + J^{k-1}, \delta v, w) \\ + (2\eta^{k-1} D\delta v, Dw) &- (\delta p, \text{div} w) - (\delta \mu \nabla \varphi^{k-1}, w) \\ - (\text{div} \delta v, q) & \\ + \frac{1}{\tau} (\delta \varphi, \Psi) &+ (b \nabla \delta \mu, \nabla \Psi) - (\delta v \varphi^{k-1}, \nabla \Psi) \\ + \sigma \epsilon (\nabla \delta \varphi, \nabla \Phi) &+ \frac{\sigma}{\epsilon} (W'_+(\varphi_h^k) \delta \varphi, \Phi) - (\delta \mu, \Phi), \end{aligned} \tag{26} \quad \{\text{eq:FD:DF}\}$$

where

$$W'_+(\varphi_h^k(x)) := \begin{cases} s & \text{if } |\varphi_h^k(x)| > 1, \\ 0 & \text{else} \end{cases} \quad \forall x \in \Omega.$$

Solving (25) leads to the numerical solution of a large linear system that we pose next.

Using the basis $\{b_2^i\} \subset V_k^2$ and $\{b_1^i\} \subset V_k^1$ we define the following matrices

and vectors:

$$\begin{aligned}
M_2 &= (m_{ij}^2)_{i,j=1}^{N_2}, \quad m_{ij}^2 := \left(\frac{\rho^{k-1} + \rho^{k-2}}{2\tau} b_2^j, b_2^i \right), \\
T_a &= (t_{ij}^a)_{i,j=1}^{N_2}, \quad t_{ij}^a := a(\rho^{k-1} v^{k-1} + J^{k-1}, b_2^j, b_2^i), \\
K_2 &= (k_{ij}^2)_{i,j=1}^{N_2}, \quad k_{ij}^2 := (2\eta^{k-1} D b_2^j, D b_2^i), \\
A &:= M_2 + T_a + K_2, \\
B &:= (b_{ij})_{i=1,\dots,N_1}^{j=1,\dots,N_2}, \quad b_{ij} = -(\operatorname{div} b_2^j, b_1^i), \\
U &:= (\xi_{ij})_{i=1,\dots,N_2}^{j=1,\dots,N_1}, \quad \xi_{ij} = -(b_1^j \nabla \varphi^{k-1}, b_2^i), \\
T &:= (t_{ij})_{i=1,\dots,N_1}^{j=1,\dots,N_2}, \quad t_{ij} = (b_2^j \varphi^{k-1}, \nabla b_1^i), \\
M_1 &:= (m_{ij}^1)_{i,j=1,\dots,N_1}, \quad m_{ij}^1 = (b_1^j, b_1^i), \\
K_1 &:= (k_{ij}^1)_{i,j=1,\dots,N_1}, \quad k_{ij}^1 = (\nabla b_1^j, \nabla b_1^i), \\
\Lambda &:= (\lambda_{ij})_{i,j=1}^{N_1}, \quad \lambda_{ij} = (W_+''(\varphi^m) b_1^j, b_1^i),
\end{aligned}$$

$$\begin{aligned}
F_1 &= (f_j^1)_{j=1}^{N_2}, \quad f_j^1 = (F^1(x^m), b_2^j), & F_2 &= (f_j^2)_{j=1}^{N_1}, \quad f_j^2 = (F^2(x^m), b_1^j), \\
F_3 &= (f_j^3)_{j=1}^{N_1}, \quad f_j^3 = (F^3(x^m), b_1^j), & F_4 &= (f_j^4)_{j=1}^{N_1}, \quad f_j^4 = (F^4(x^m), b_1^j).
\end{aligned}$$

Here, φ^m denotes the m -th iterate of Newton's method for the approximation of φ_h^k . Equation (25) can then be written as

$$\left(\begin{array}{cc|cc} A & B^t & 0 & U \\ B & 0 & 0 & 0 \\ \hline T & 0 & \tau^{-1} M_1 & b K_1 \\ 0 & 0 & \sigma \epsilon K_1 + \sigma \epsilon^{-1} \Lambda & -M_1 \end{array} \right) \begin{pmatrix} \delta v \\ \delta p \\ \delta \varphi \\ \delta \mu \end{pmatrix} = \begin{pmatrix} F_1 \\ F_2 \\ F_3 \\ F_4 \end{pmatrix}, \quad (27) \quad \{\text{eq:FD:LS}\}$$

where $\delta v, \delta p, \delta \mu, \delta \varphi$ denote the node vectors for $\delta v, \delta p, \delta \varphi, \delta \mu$. In the following, we denote the coefficient matrix in (27) by $\mathcal{A}$. We can further write $\mathcal{A}$ as

$$\mathcal{A} = \left(\begin{array}{c|c} A_{\text{NS}} & C_I \\ \hline C_T & A_{\text{CH}} \end{array} \right), \quad (28) \quad \{\text{eq:FD:LS_short}\}$$

where the blocks A_{NS} and A_{CH} are the discrete realizations of the linearized Navier–Stokes and Cahn–Hilliard system, respectively. Their coupling is represented by C_I , the coupling through the interfacial force, and C_T , the coupling through the transport at the interface.

3 Preconditioning

As we have seen in the previous section, a large and sparse linear nonsymmetric system is at the heart of the computation. In [GHK16], the system (27) is solved

by preconditioned GMRES [SS86] with a restart after 10 iterations. The authors use the block diagonal preconditioner

$$\mathcal{P} = \begin{pmatrix} \hat{A}_{\text{NS}} & \mathbf{0} \\ \mathbf{0} & A_{\text{CH}} \end{pmatrix}. \quad (29) \quad \{\text{eq:FD:LS:P_GHK}\}$$

The (2,2) block A_{CH} is inverted by LU decomposition. The (1,1) block $\hat{A}_{\text{NS}}$ is an upper block triangular preconditioner of the form

$$\hat{A}_{\text{NS}} = \begin{pmatrix} \hat{A} & B^t \\ 0 & \hat{S}_{\text{NS}} \end{pmatrix}. \quad (30) \quad \{\text{chap3:CHNS:NS_prec}\}$$

$\hat{A}$ is composed of the diagonal blocks of A and is inverted by LU decomposition. $\hat{S}_{\text{NS}}$ is an approximation of the exact Schur complement $S_{\text{NS}} = -BA^{-1}B^t$ of the Navier–Stokes system. Garcke et al. [GHK16] use

$$\hat{S}_{\text{NS}} = -K_p A_p^{-1} M_p, \quad (31) \quad \{\text{chap3:CHNS:NS_Schur_prec}\}$$

where A_p is the representation of A on the pressure space, K_p the pressure Laplacian matrix, and M_p and the pressure mass matrix. This Schur complement approximation was proposed, e.g., in [KLW02, EJV05], where it was shown to be independent of the mesh size and only mildly dependent on the Reynolds number.

Now, the current paper concerns the fully iterative solution of the system (27). This is based on the preconditioning techniques that have been developed in [BSB14] for the nonsmooth Cahn–Hilliard system together with the methods that have been developed in [KLW02, EJV05] for the Navier–Stokes equations. We first rewrite (27) to

$$\left(\begin{array}{cc|cc} A & B^t & U & 0 \\ B & 0 & 0 & 0 \\ \hline 0 & 0 & M_1 & -\sigma\epsilon K_1 - \sigma\epsilon^{-1}\Lambda \\ \tau T & 0 & \tau b K_1 & M_1 \end{array} \right) \begin{pmatrix} \delta v \\ \delta p \\ \delta \mu \\ \delta \varphi \end{pmatrix} = \begin{pmatrix} F_1 \\ F_2 \\ -F_4 \\ F_3 \end{pmatrix}. \quad (32) \quad \{\text{eq:FD:LS2}\}$$

In the following, we denote the coefficient matrix in (32) by $\mathcal{A}$. As before, we can write $\mathcal{A}$ as

$$\mathcal{A} = \begin{pmatrix} A_{\text{NS}} & C_I \\ C_T & A_{\text{CH}} \end{pmatrix}. \quad (33) \quad \{\text{eq:FD:LS2_short}\}$$

For the sake of simplicity, we use the same notation as in (28), but keep in mind that the block matrices in (28) and (33) differ. Our basis for preconditioning is the upper block triangular preconditioner

$$\mathcal{P} = \begin{pmatrix} A_{\text{NS}} & C_I \\ \mathbf{0} & S \end{pmatrix},$$

motivated in [EJW05, MGW00], where $S = A_{\text{CH}} - C_T A_{\text{NS}}^{-1} C_I$ is the Schur complement of the whole system. The right-preconditioned matrix becomes

$$\mathcal{AP}^{-1} = \left(\begin{array}{c|c} I & \mathbf{0} \\ \hline C_T A_{\text{NS}}^{-1} & I \end{array} \right),$$

where I is the identity matrix. Hence, $\mathcal{AP}^{-1}$ has only a single eigenvalue of 1, and $\mathcal{P}$ is called a theoretical optimal preconditioner.¹ This preconditioner needs the application of the inverse of A_{NS} and of S , which cannot be explicitly used. Hence, our aim is the development of practical approximations $\hat{A}_{\text{NS}} \approx A_{\text{NS}}$ and $\hat{S} \approx S$, which leads to our practical preconditioner

$$\mathcal{P}_{\text{out}} = \left(\begin{array}{cc} \hat{A}_{\text{NS}} & C_I \\ \mathbf{0} & \hat{S} \end{array} \right). \quad (34) \quad \{\text{eq:FD:LS:P}\}$$

Note that the index of $\mathcal{P}_{\text{out}}$ marks an outer preconditioner. Below in Section 3.2, we will introduce an inner preconditioner for the solution of linear systems with $\hat{S}$. For good approximations $\hat{A}_{\text{NS}} \approx A_{\text{NS}}$ and $\hat{S} \approx S$, the preconditioned matrix $\mathcal{AP}_{\text{out}}^{-1}$ has only a small number of different eigenvalue clusters. This in turn is known to result in only a few iterations of suitable Krylov subspace solvers until convergence [EJW05, MGW00].

3.1 Approximation of A_{NS}

Similar to Garcke et al. [GHK16] in (30), we choose $\hat{A}_{\text{NS}}$ as

$$\hat{A}_{\text{NS}} = \left(\begin{array}{cc} \hat{A} & B^t \\ \mathbf{0} & -\hat{S}_{\text{NS}} \end{array} \right). \quad (35) \quad \{\text{eq:FD:LS:P_NS}\}$$

As above, $\hat{A}$ is composed of the diagonal blocks of A . We use an algebraic multigrid (AMG) preconditioner² for the approximation of the inverse of $\hat{A}$. As shown in [Ram99], multigrid is a good preconditioner for convection-diffusion problems if the Reynolds number is not too large. $\hat{S}_{\text{NS}}$ is given in (31). The action of the inverse of M_p and K_p are performed with an AMG each. Note that the conjugate gradient method with Jacobi preconditioning provides a good approximation to the inverse of M_p as well, see e.g. [KLW02]. K_p is a discrete Laplacian for which multigrid provides a good approximation to the inverse; see [Wes92].

¹Note, that the left-preconditioned system $\mathcal{P}^{-1}\mathcal{A}$ has the same spectrum as the right-preconditioned system $\mathcal{AP}^{-1}$.

²AMG methods typically exhibit geometric-like properties for positive definite elliptic type operators but use only algebraic information. This has the advantage that AMG can work well even for complicated geometries and meshes. We refer to [RS87, Fal06] for more information on AMG. We also want to emphasize that geometric multigrid (see, e.g., [Wes92, Hac85]) approximations are also well suited to approximate $\hat{A}$ provided they can be readily applied.

3.2 Approximation of S

Now, let us consider the Schur complement $S = A_{\text{CH}} - C_T A_{\text{NS}}^{-1} C_I$ of the whole system. Using the preconditioner $\hat{A}_{\text{NS}}$ from the previous section, we approximate S as

$$S \approx A_{\text{CH}} - C_T \hat{A}_{\text{NS}}^{-1} C_I = \begin{pmatrix} M_1 & -\sigma\epsilon K_1 - \sigma\epsilon^{-1}\Lambda \\ \tau b K_1 - \tau T \hat{A}^{-1} U & M_1 \end{pmatrix} =: \hat{S}.$$

We propose to apply a preconditioned GMRES iteration to the system of the form $\hat{S}y = f$. We call this iteration the inner iteration. For the construction of the preconditioner $\mathcal{P}_{\text{in}}$ for the inner iteration, we make use of the following formulation:

$$\hat{S} = \begin{pmatrix} M_1 & -\sigma\epsilon K_1 - \sigma\epsilon^{-1}\Lambda \\ \tau b K_1 & M_1 \end{pmatrix} - \begin{pmatrix} 0 & 0 \\ \tau T \hat{A}^{-1} U & 0 \end{pmatrix} = A_{\text{CH}} - \begin{pmatrix} 0 & 0 \\ \tau T \hat{A}^{-1} U & 0 \end{pmatrix} \approx A_{\text{CH}}.$$

Hence, we build the preconditioner $\mathcal{P}_{\text{in}}$ for the inner iteration on the basis of the simplification A_{CH} of $\hat{S}$. Now, one might ask why we do not further simplify $\hat{S}$ or A_{CH} to

$$\mathring{A}_{\text{CH}} = \begin{pmatrix} M_1 & -\sigma\epsilon K_1 \\ \tau b K_1 & M_1 \end{pmatrix},$$

since optimal preconditioners exist for matrices of this form; see e.g. [AN11, BDQN11]. However, the following theorem states the severe influence of the penalty parameter s contained in Λ ; see also [Bos16]. Hence, a simplification to $\mathring{A}_{\text{CH}}$ would give a worse approximation for large values of s .

For the following theorem, we make use of the symmetric positive definiteness of M_1 as well as of the symmetric positive semidefiniteness of K_1 and Λ .

Theorem 9. *It holds*

$$\sigma(\hat{A}_{\text{CH}}^{-1} A_{\text{CH}}) \subset B_\varsigma(1),$$

where $B_\varsigma(1)$ is a circle in the complex plane around one with radius ς . The radius is bounded by $\varsigma \leq \frac{s\sqrt{\tau\sigma b}}{2\epsilon\sqrt{\epsilon}} \rho(\tilde{\Lambda}_0)$, where $\tilde{\Lambda}_0 = s^{-1} M_1^{-\frac{1}{2}} \Lambda M_1^{-\frac{1}{2}}$. In particular, N_1 eigenvalues are equal to one. We get $\varsigma \leq 0.5$ when $\tau < \epsilon^3 / (s^2 \sigma b \rho(\tilde{\Lambda}_0)^2)$. In particular, in the case of lumped mass matrices, we have $\rho(\tilde{\Lambda}_0) = 1$ and hence, the circle radius is bounded by $\varsigma \leq \frac{s\sqrt{\tau\sigma b}}{2\epsilon\sqrt{\epsilon}}$. Hence, we get $\varsigma \leq 0.5$ when $\tau < \epsilon^3 / (s^2 \sigma b)$.

Proof. Consider the generalized eigenvalue problem

$$A_{\text{CH}} \begin{bmatrix} q_1 \\ q_2 \end{bmatrix} = \lambda \mathring{A}_{\text{CH}} \begin{bmatrix} q_1 \\ q_2 \end{bmatrix}. \quad (36) \quad \{\text{eq:FD:LS:S_GEP}\}$$

We transform (36) to

$$(A_{\text{CH}} - \mathring{A}_{\text{CH}}) \begin{bmatrix} q_1 \\ q_2 \end{bmatrix} = \mu \mathring{A}_{\text{CH}} \begin{bmatrix} q_1 \\ q_2 \end{bmatrix}, \quad (37) \quad \{\text{eq:FD:LS:S_GEP:2}\}$$

where $\mu = \lambda - 1$. The inverse of $\mathring{A}_{\text{CH}}$ can be expressed via the Schur complement $\mathring{S}_{\text{CH}} = M_1 + \sigma\epsilon\tau b K_1 M_1^{-1} K_1$ of $\mathring{A}_{\text{CH}}$ as

$$\mathring{A}_{\text{CH}}^{-1} = \begin{bmatrix} \mathring{S}_{\text{CH}}^{-1} & \sigma\epsilon\mathring{S}_{\text{CH}}^{-1} K_1 M_1^{-1} \\ -\tau b \mathring{S}_{\text{CH}}^{-1} K_1 M_1^{-1} & \mathring{S}_{\text{CH}}^{-1} \end{bmatrix}. \quad (38) \quad \{\text{eq:FD:LS:S_GEP:3}\}$$

This yields

$$\mathring{A}_{\text{CH}}^{-1}(\mathring{A}_{\text{CH}} - \mathring{A}_{\text{CH}}) = \begin{bmatrix} 0 & -\sigma\epsilon^{-1}\mathring{S}_{\text{CH}}^{-1}\Lambda \\ 0 & \tau\sigma b\epsilon^{-1}\mathring{S}_{\text{CH}}^{-1}K_1 M_1^{-1}\Lambda \end{bmatrix}. \quad (39) \quad \{\text{eq:FD:LS:S_GEP:4}\}$$

Hence, (37) has N_1 zero eigenvalues corresponding to eigenvectors $[q_1^T, 0^T]^T$. Thus, (36) has N_1 one eigenvalues. Next, we write (37) as

$$-\sigma\epsilon^{-1}\Lambda q_2 = \mu(M_1 q_1 - \sigma\epsilon K_1 q_2), \quad (40) \quad \{\text{eq:FD:LS:S_GEP:5a}\}$$

$$0 = \mu(\tau b K_1 q_1 + M_1 q_2). \quad (41) \quad \{\text{eq:FD:LS:S_GEP:5b}\}$$

We express μq_1 from (40) and substitute it into (41) to obtain

$$\tau\sigma b\epsilon^{-1}K_1 M_1^{-1}\Lambda q_2 = \mu(\tau\sigma b\epsilon K_1 M_1^{-1}K_1 + M_1)q_2.$$

Multiplying this equation from the left by M_1^{-1} yields the following generalized eigenvalue problem

$$\tau\sigma b\epsilon^{-1}M_1^{-1}K_1 M_1^{-1}\Lambda q_2 = \mu(I + \tau\sigma b\epsilon(M_1^{-1}K_1)^2)q_2,$$

where I is the identity matrix. We introduce

$$R := \tau\sigma b\epsilon^{-1}(I + \tau\sigma b\epsilon(M_1^{-1}K_1)^2)^{-1} M_1^{-1}K_1 M_1^{-1}\Lambda$$

and estimate its eigenvalues in the following. Therefore, we first perform a similarity transformation on R : $M_1^{\frac{1}{2}} R M_1^{-\frac{1}{2}} =: \tilde{R}$. Note that R and $\tilde{R}$ have the same eigenvalues. Next, we analyze the eigenvalues of $\tilde{R}$. Therefore, we first reformulate $\tilde{R}$ as

$$\begin{aligned} \tilde{R} &= \tau\sigma b\epsilon^{-1}M_1^{\frac{1}{2}}(I + \tau\sigma b\epsilon(M_1^{-1}K_1)^2)^{-1} M_1^{-1}K_1 M_1^{-1}\Lambda M_1^{-\frac{1}{2}} \\ &= \tau\sigma b\epsilon^{-1}\left[(I + \tau\sigma b\epsilon(M_1^{-1}K_1)^2)M_1^{-\frac{1}{2}}\right]^{-1} M_1^{-1}K_1 M_1^{-1}\Lambda M_1^{-\frac{1}{2}} \\ &= \tau\sigma b\epsilon^{-1}\left(M_1^{-\frac{1}{2}} + \tau\sigma b\epsilon(M_1^{-1}K_1)^2 M_1^{-\frac{1}{2}}\right)^{-1} M_1^{-1}K_1 M_1^{-1}\Lambda M_1^{-\frac{1}{2}} \\ &= \tau\sigma b\epsilon^{-1}\left[M_1^{-\frac{1}{2}}\left(I + \tau\sigma b\epsilon M_1^{-\frac{1}{2}}K_1 M_1^{-1}K_1 M_1^{-\frac{1}{2}}\right)\right]^{-1} M_1^{-1}K_1 M_1^{-1}\Lambda M_1^{-\frac{1}{2}} \\ &= \tau\sigma b\epsilon^{-1}\left(I + \tau\sigma b\epsilon M_1^{-\frac{1}{2}}K_1 M_1^{-1}M_1^{-\frac{1}{2}}K_1 M_1^{-\frac{1}{2}}\right)^{-1} M_1^{-\frac{1}{2}}K_1 M_1^{-\frac{1}{2}}M_1^{-\frac{1}{2}}\Lambda M_1^{-\frac{1}{2}} \\ &= \tau\sigma b\epsilon^{-1}\left(I + \tau\sigma b\epsilon\tilde{K}_1^2\right)^{-1} \tilde{K}_1 \tilde{\Lambda}, \end{aligned} \quad (42) \quad \{\text{eq:FD:LS:S_GEP:6}\}$$

where $\tilde{K}_1 = M_1^{-\frac{1}{2}} K_1 M_1^{-\frac{1}{2}}$ and $\tilde{\Lambda} = M_1^{-\frac{1}{2}} \Lambda M_1^{-\frac{1}{2}}$. Note that $\tilde{K}_1$ and $\tilde{\Lambda}$ are symmetric positive semidefinite. Hence, using the symmetric Schur decomposition, we can write $\tilde{K}_1 = V D V^T$, where $V = [v_1 | \dots | v_{N_1}] \in \mathbb{R}^{N_1 \times N_1}$ is orthogonal and $D = \text{diag}(\lambda_1, \dots, \lambda_{N_1})$ such that $\tilde{K}_1 v_j = \lambda_j v_j$ for $j = 1, \dots, N_1$. Hence, $\tilde{K}_1^2 = V D^2 V^T$. Using this Schur decomposition, we can rewrite $(I + \tau \sigma b \epsilon \tilde{K}_1^2)^{-1} \tilde{K}_1$ in (42) further as

$$\begin{aligned} (I + \tau \sigma b \epsilon \tilde{K}_1^2)^{-1} \tilde{K}_1 &= (V V^T + \tau \sigma b \epsilon V D^2 V^T)^{-1} V D V^T = [V (V^T + \tau \sigma b \epsilon D^2 V^T)]^{-1} V D V^T \\ &= (V^T + \tau \sigma b \epsilon D^2 V^T)^{-1} D V^T = [(I + \tau \sigma b \epsilon D^2) V^T]^{-1} D V^T \\ &= V (I + \tau \sigma b \epsilon D^2)^{-1} D V^T, \end{aligned}$$

where $(I + \tau \sigma b \epsilon D^2)^{-1} D$ is a diagonal matrix. Hence, $(I + \tau \sigma b \epsilon \tilde{K}_1^2)^{-1} \tilde{K}_1$ is symmetric. It follows that

$$(I + \tau \sigma b \epsilon \tilde{K}_1^2)^{-1} \tilde{K}_1 v_j = \frac{\lambda_j}{1 + \lambda_j^2 \tau \sigma b \epsilon} v_j \quad (43) \quad \{\text{eq:FD:LS:S_GEP:7}\}$$

for $j = 1, \dots, N_1$. Using the inequality

$$0 \leq (1 - \alpha\beta)^2 = 1 + \alpha^2\beta^2 - 2\alpha\beta$$

with $\alpha, \beta \in \mathbb{R}$, we can bound the eigenvalues of (43) as

$$\frac{\lambda_j}{1 + \lambda_j^2 \tau \sigma b \epsilon} \leq \frac{\lambda_j}{2\lambda_j \sqrt{\tau \sigma b \epsilon}} = \frac{1}{2\sqrt{\tau \sigma b \epsilon}}$$

for $j = 1, \dots, N_1$. Here, we have used $\alpha^2 = \tau \sigma b \epsilon$ and $\beta^2 = \lambda_j^2$. This yields

$$\rho\left((I + \tau \sigma b \epsilon \tilde{K}_1^2)^{-1} \tilde{K}_1\right) \leq \frac{1}{2\sqrt{\tau \sigma b \epsilon}}. \quad (44) \quad \{\text{eq:FD:LS:S_GEP:8}\}$$

Finally, we can estimate the eigenvalues of $\tilde{R}$. Note that it holds $\rho(\tilde{R}) \leq \|\tilde{R}\|$; see e.g. [Saa03, p. 115]. Further, we obtain

$$\begin{aligned} \|\tilde{R}\| &\leq \tau \sigma b \epsilon^{-1} \|(I + \tau \sigma b \epsilon \tilde{K}_1^2)^{-1} \tilde{K}_1\| \|\tilde{\Lambda}\| = \tau \sigma b \epsilon^{-1} \rho\left((I + \tau \sigma b \epsilon \tilde{K}_1^2)^{-1} \tilde{K}_1\right) \rho(\tilde{\Lambda}) \\ &\leq \frac{\sqrt{\tau \sigma b}}{2\epsilon \sqrt{\epsilon}} \rho(\tilde{\Lambda}), \end{aligned} \quad (45) \quad \{\text{eq:FD:LS:S_GEP:9}\}$$

where the equality holds due to the symmetry of $(I + \tau \sigma b \epsilon \tilde{K}_1^2)^{-1} \tilde{K}_1$ and $\tilde{\Lambda}$. In order to illustrate the influence of the penalty parameter s , we reformulate $\tilde{\Lambda}$ as

$$\tilde{\Lambda} = M_1^{-\frac{1}{2}} \Lambda M_1^{-\frac{1}{2}} = s M_1^{-\frac{1}{2}} \Lambda_0 M_1^{-\frac{1}{2}} = s \tilde{\Lambda}_0,$$

where $\Lambda_0 = (\lambda_{ij}^0)_{ij=1}^{N_1}$, $\lambda_{ij}^0 = (W''_{+,0}(\varphi^m)b_1^j, b_1^i)$, and

$$W''_{+,0}(\varphi_h^k(x)) := \begin{cases} 1 & \text{if } |\varphi_h^k(x)| > 1, \\ 0 & \text{else} \end{cases} \quad \forall x \in \Omega.$$

Hence, we have

$$\|\tilde{R}\| \leq \frac{s\sqrt{\tau\sigma b}}{2\epsilon\sqrt{\epsilon}} \rho(\tilde{\Lambda}_0), \quad (46) \quad \{\text{eq:FD:LS:S_GEP:10}\}$$

where $\rho(\tilde{\Lambda}_0)$ depends on the spatial mesh size and φ_h^k . Therefore, for $\tau < \epsilon^3/(s^2\sigma b\rho(\tilde{\Lambda}_0)^2)$, it holds $\sigma(\tilde{R}) = \sigma(R) \subset B_{0.5}(0)$ and hence $\sigma(\hat{A}_{CH}^{-1}A_{CH}) \subset B_{0.5}(1)$.

In the case of lumped mass matrices, $\tilde{\Lambda}_0$ becomes a diagonal matrix with entries that are either zero or one. Thus, we obtain in (46)

$$\|\tilde{R}\| \leq \frac{s\sqrt{\tau\sigma b}}{2\epsilon\sqrt{\epsilon}}.$$

Therefore, for $\tau < \epsilon^3/(s^2\sigma b)$, it holds $\sigma(\tilde{R}) = \sigma(R) \subset B_{0.5}(0)$ and hence $\sigma(\hat{A}_{CH}^{-1}A_{CH}) \subset B_{0.5}(1)$. $\square$

Hence, neglecting the block Λ would only be satisfying for tiny time step sizes τ , which is far away from being practical.

As preconditioner for the inner iteration, we propose the upper block triangular preconditioner

$$\mathcal{P}_{\text{in}} = \begin{bmatrix} M_1 & -\sigma\epsilon K_1 - \sigma\epsilon^{-1}\Lambda \\ 0 & -\hat{S}_{CH} \end{bmatrix}. \quad (47) \quad \{\text{eq:FD:LS:P_CH}\}$$

$\hat{S}_{CH}$ is an approximation of the exact Schur complement

$$S_{CH} = M_1 + \tau(bK_1 - T\hat{A}^{-1}U)M_1^{-1}(\sigma\epsilon K_1 + \sigma\epsilon^{-1}\Lambda)$$

of $\hat{S}$. Our procedure for the approximation of the Schur complement S_{CH} originates in the work of Pearson and Wathen [PW12], who developed preconditioners for PDE-constrained optimization. Their matching strategy, applied to our problem, is the following: Construct a preconditioner of the form $\hat{S}_{CH} = S_1M_1^{-1}S_2$, which captures the exact Schur complement S_{CH} as close as possible. Note that we need $\hat{S}_{CH}$ to be nonsingular. We design $\hat{S}_{CH}$ as

$$\begin{aligned} \hat{S}_{CH} &= S_1M_1^{-1}S_2 \\ &= (M_1 + \sqrt{\tau\sigma b}K_1)M_1^{-1}(M_1 + \sqrt{\tau b\sigma^{-1}}[\sigma\epsilon K_1 + \sigma\epsilon^{-1}\Lambda]) \\ &= M_1 + \tau bK_1M_1^{-1}(\sigma\epsilon K_1 + \sigma\epsilon^{-1}\Lambda) + \sqrt{\tau b\sigma}K_1 + \sqrt{\tau b\sigma}(\epsilon K_1 + \epsilon^{-1}\Lambda). \end{aligned} \quad (48) \quad \{\text{eq:FD:LS:P_CH_Schur}\}$$

The first term in (48) matches the first term in the exact Schur complement. The second term in (48) approximates the second term in the exact Schur complement. Due to the factor $\sqrt{\tau b \sigma}$, the influence of both remainder terms in (48) is reduced. We refer the reader to [BSB14, BKS14, BS15, Bos16] for Schur complement approximations to other Cahn–Hilliard problems. The action of the inverse of S_1 and S_2 is performed with an AMG each since both form the discretization of an elliptic operator. We also apply AMG for the action of the inverse of the $(1, 1)$ block M_1 in $\mathcal{P}_{\text{in}}$.³

Here, we finish the theoretical discussion about the preconditioner. In the next section, we illustrate its efficiency via various numerical experiments.

4 Numerical examples

In this section, we show numerical results for the presented coupled Cahn–Hilliard Navier–Stokes problem. First, we explain our implementation framework.

Garcke et al. [GHK16] have implemented the whole numerical simulation in C++. We use their code, but the iterative solution of the linear system is executed in MATLAB® R2012a on a 32-bit server with CPU type Intel® Core™ E6850 @3.00 GHz with 2 CPUs. We use the MATLAB Engine API in order to call MATLAB® from C++.

As we use GMRES as the inner iteration, we apply FGMRES as the outer iteration. FGMRES is a variant of GMRES and was introduced by Saad [Saa93]. This method allows changes in the preconditioner at every step. Note again that we apply right preconditioning here. We use FGMRES (outer solver) with a restart after 30 iterations and set the initial guess to the zero vector. As stopping criterion, we use

$$\|\mathbf{b} - \mathcal{A}\mathbf{z}^{(l)}\| \leq \min(10^{-6} \|\mathbf{b}\|, 10^{-6}),$$

where $\mathbf{b}$ denotes the corresponding right-hand side and $\mathbf{z}^{(l)}$ the calculated solution at FGMRES step l . We use GMRES (inner solver) without restart and set the initial guess to the zero vector, the tolerance for the preconditioned relative residual to 10^{-1} , and the maximum number of iterations to 50.

For the application of AMG, we employ the HSL (formerly the Harwell Subroutine Library) Mathematical Software Library, a collection of Fortran codes for large-scale scientific computation; see <http://www.hsl.rl.ac.uk/> and [BMS10]. In particular, we make use of the *HSL_MI20* package for the approximation of the inverse of $\hat{A}$ (the two diagonal blocks of the discrete convection-diffusion operator) and of K_p (the pressure Laplacian matrix). For

³For consistent mass matrices, the Chebyshev-iteration [GV61a, GV61b] provides a powerful preconditioner [WR09, RS10].

$\hat{A}$, we apply *HSL_MI20* with two coarse levels in the multigrid structure, two V-cycles with symmetric Gauss–Seidel smoothing (two pre- and two post-smoothing iterations), and 10 Gauss–Seidel iterations on the coarsest level. For K_p , we apply *HSL_MI20* with at most 100 coarse levels in the multigrid structure, one V-cycle with symmetric Gauss–Seidel smoothing (two pre- and two post-smoothing iterations), and the sparse direct solver *HSL_MA48* on the coarsest level.

Moreover, we employ the software package *AGMG* version 3.2.0, a program which implements AMG described in [Not10] with further improvements from [NN12] and [Not12]; see also <http://homepages.ulb.ac.be/~ynotay/AGMG>. It introduces K-cycle multigrid meaning that the iterative solution of the residual equation at each level is accelerated with a Krylov subspace method. We use the default, which is a preconditioned variant of the generalized conjugate residual method (GCR) [EES83] restarted every 10 iterations. We set the maximum number of iterations to 50. The coarsening is stopped when the coarse grid matrix has 200 or less rows, allowing fast direct inversion with LAPACK routines [ABB⁺99]. Symmetric Gauss–Seidel smoothing is used with one pre- and one post-smoothing iteration. We make use of the *AGMG* MATLAB interface for the approximation of the inverse of M_p (the pressure mass matrix), of M_1 (the (1,1) block of the inner preconditioner $\mathcal{P}_{\text{in}}$), as well as of S_1 and S_2 (the two blocks forming the Schur complement approximation $\hat{S}_{CH}$). If not mentioned otherwise, we set the tolerance on the relative residual norm to 10^{-3} , 10^{-2} , 10^{-5} , and 10^{-5} for M_p , M_1 , S_1 , and S_2 , respectively.

4.1 Parameter study: A rising bubble

In this section, we demonstrate the robustness of our proposed preconditioner regarding relevant model parameters. As test example, we use a quantitative benchmark for rising bubble dynamics; see the first benchmark test case in [HTK⁺09]. A simulation is illustrated in Figure 1.

Figure 1: Simulation of a rising bubble using a coupled Cahn–Hilliard Navier–Stokes model.

The initial configuration is described as follows; see also [GHK16, p. 168]. The spatial domain is $\Omega = (0, 1) \times (0, 2)$ with no-slip boundary conditions for

the velocity field on the top and bottom wall and free-slip boundary conditions on the left and right wall. The initial state consists of a bubble of radius $r = 0.25$ centered at the spatial point $(0.5, 0.5)$. The initial velocity is zero. In the following, we denote by N_1^0 and N_2^0 the values of N_1 and N_2 and time 0. The fixed parameters in all tests are given as $\rho_2 = 100$, $\eta_1 = 10$, $\eta_2 = 1$, $g = (0, -0.98)^t$. The remaining parameters are given below for each individual experiment. Moreover, the Reynolds number is given as

$$Re = \frac{0.35 \rho_1}{\eta_1}.$$

Figures 2 and 3 demonstrate the robustness with respect to different model parameters. Table 1 shows the values of all parameters. In Figure 2(a), we simultaneously vary the mesh sizes via refinements of the initial spatial mesh $\mathcal{T}^0$, the interfacial parameter ϵ , the time step size τ , as well as the mobility b . In fact, this is the practical procedure: Choose an ϵ and adjust the mesh sizes. The time step size is adapted to fulfill the CFL-condition. Moreover, the mobility is chosen to be $b = 10^{-3}\epsilon$, as used in [GHK16, p. 168]. Except for the initial time frame, we observe a robust behavior of iteration numbers. In Figure 2(b), we vary the scaled surface tension σ . Although the iteration numbers behave quite chaotic, they mostly stay in the range between 50 and 65. In Figure 2(c), we vary the Reynolds number via increasing the density ρ_1 . We observe a small increase of iterations numbers as the Reynolds number increases. In Figure 3(a), we vary the mobility b . We observe a benign increase of iterations numbers as the mobility decreases. In Figure 3(b), we vary the penalty parameter s . Comparing the iteration numbers for $s = 10^4$ with the ones for $s \in \{10^6, 10^8, 10^9\}$, we even obtain better results for the larger penalty parameters. Finally, Table 1 illustrates the maximum and average number of semismooth Newton iterations for each of the five subplots, respectively.

In summary, we observe a rather robust behavior of the iterative method with respect to changes of the parameters of the system. Especially, the method is robust with respect to the parameter ϵ , that heavily influences the number of degrees of freedom and therefore the size of the linear system, and the parameter s for which we typically observe a severe increase of the condition number.

4.2 A topology change

In this section, we demonstrate the behavior of our preconditioner under topology changes. As test example, we use a quantitative benchmark for rising bubble dynamics; see the second benchmark in [HTK⁺09]. It considers a bubble with a very low density compared to that of the surrounding fluid. The initial configuration is the same as in the previous benchmark example. The parameters are given as $\rho_1 = 1000$, $\rho_2 = 1$, $\eta_1 = 10$, $\eta_2 = 0.1$, $Re = 35$, $N_1^0 = 4513$, $N_2^0 = 17929$, $\epsilon = 0.04$, $\tau = 0.002$, $b = 4 \cdot 10^{-5}$, $\sigma = 1.24777$, $s = 10^6$. As stated

(a) Simultaneous variation of the initial spatial mesh $\mathcal{T}^0$, the interfacial parameter ϵ , the time step size τ , as well as the mobility b .

(b) Variation of the scaled surface tension σ .

(c) Variation of the Reynolds number via increasing the density ρ_1 .

Figure 2: Iteration numbers for the parameter study. The x-axis shows the time step and the y-axis the average number of FGMRES iterations per semismooth Newton step.

(a) Variation of the mobility b .

(b) Variation of the penalty parameter s .

Figure 3: Iteration numbers for the parameter study. The x-axis shows the time step and the y-axis the average number of FGMRES iterations per semismooth Newton step.

Table 1: The maximum and average number of semismooth Newton iterations for each parameter test.

in [AV12, p. 756], the decrease in surface tension causes the bubble to develop a more non-convex shape and thin filaments, which eventually break off. A simulation of this benchmark test example is illustrated in Figure 4.

Figure 4: Simulation of a rising bubble under topology changes using a coupled Cahn–Hilliard Navier–Stokes model.

In this example, we set the tolerance on the relative residual norm for S_1 and S_2 to 10^{-6} . Figure 5 demonstrates the average number of FGMRES iterations per semismooth Newton step during the time interval $[0, 0.56]$, which consists of 280 time steps. Since the crucial part is the period during the topology change, we show the corresponding iteration numbers in Table 2. Note that for the results in Table 2, we do not call MATLAB[®] from C++. Instead, we use Garcke et al’s [GHK16] original C++ implementation, write the matrices and right-hand sides into text files, and solve the problems in MATLAB using our developed preconditioner. There are two reasons for this procedure: First, it takes a lot of time to get to the crucial instant of time using C++ with the MATLAB Engine API. Second, we observe abnormal terminations after long program runs. Hence, an important step for future research is an implementation of our preconditioner in C++ such that the MATLAB Engine API would be no longer required. Further, we set the GMRES (inner solver) tolerance for the preconditioned relative residual to 10^{-2} . Table 2 shows that the FGMRES iteration numbers stay quite robust under topology changes.

Table 2: Iteration numbers for the rising bubble under topology changes. The table shows the time with the average number of FGMRES iterations per semismooth Newton step.

5 Conclusions

In this paper, we have investigated the efficient iterative solution of the linear systems arising in Abels et al’s [AGG12] diffuse interface model for incom-

Figure 5: Iteration numbers for the second benchmark example. The x-axis shows the time step and the y-axis the average number of FGMRES iterations per semismooth Newton step.

pressible two-phase flows with different densities. It couples the Navier–Stokes equations to the Cahn–Hilliard model in a thermodynamically consistent way, i.e., an energy inequality holds. Thereby, we have drawn on the consistent discretization scheme developed by Garcke et al. [GHK16]. At the heart of this method lies the solution of large and sparse linear systems that arise in a semismooth Newton method. The systems to be solved are fully coupled. We have introduced and studied block-triangular preconditioners using efficient Schur complement approximations. For these approximations, we have used multilevel techniques, algebraic multigrid in our case. Extensive numerical experiments show a nearly parameter independent behavior of our developed preconditioners. Together with Garcke et al’s [GHK16] adaptive spatial discretization scheme, this allows us to perform three-dimensional experiments in an efficient way. This will be subject to future work.
